# Randomization of Sparse Matrix by Vector Multiplication

# ABHISHEK JAIN, ISMAIL BUSTANY, and PAOLO D'ALBERTO

A sparse matrix by vector multiplication (SpMV) is simplified by the matrix non-zero elements and how we store them. There are many SpMV applications, many matrix storage formats, and thus algorithms. However, there is no optimality without considering the architecture: for example, the CPU is only one among ... many.

By nature, randomization is resilient to counter techniques, thus suitable to avoid worst case scenarios because we tend to reduce to an average case; however, it does to the best case the same thing it does to the worst case, it can nudge it off. Like preconditioning, randomization is advantageous when the matrix is reused or a constant such as in the power method, Krilov's space, or convolutions for image classifications. Differently from preconditioning we randomize row and column of the matrix. We shall show that randomization is an optimization that any architecture may take advantage although in different ways. Most importantly, any developer can consider and deploy.

We shall present cases where we can improve performance by 15%, yes by just permuting rows and columns of the original sparse matrix.

### 1 INTRODUCTION

B.S. Goes here.

### **2 BASIC NOTATIONS**

Let us start by describing the basic notations so we can clear the obvious (or not). A Sparse-matrix by vector multiplication SpMV on an (semi) ring based on the operations (+,\*) is defined as  $\mathbf{y} = \mathbb{M}\mathbf{x}$  so that  $y_i = \sum_j M_{i,j} * y_j$  where  $M_{i,j} = 0$  are not even represented and stored. Most of the experimental results in Section 9 are based on the classic addition (+) and multiplication (\*) in floating point precision using 64bits (i.e., double floating point precision). SpMV based on semi-ring (min,+) is a short path algorithm based on an adjacent matrix of a graph, and using a Boolean algebra we can check if two nodes are connected, which is slightly simpler.

We identify a sparse matrix  $\mathbb{M}$  of size  $M \times N$  as having O(M + N) non-zero elements, number of non zero nnz. Thus the complexity of  $\mathbb{M}\mathbf{x}$  is O(M + N) = 2nnz. Of course, the definition of sparsity may vary. We represent the matrix  $\mathbb{M}$  by using the Coordinate COO or and the compressed sparse row  $CSR^1$  format. The COO represents the non-zero of a matrix by a triplet (i, j, val), very often there are three identical-in-size vectors for the ROW, COLUMN, and VALUE.

Manuscript submitted to ACM

<sup>&</sup>lt;sup>1</sup>a.k.a. Compressed row storage CRS.

The COO format takes  $3 \times nnz$  space and two consecutive elements in the value array are not bound to be neither in the same row nor column. In fact, we know only that  $VALUE[i] = M_{ROW[i],COLUMN[i]}$ .

The CSR stores elements in the same row and with increasing column values consecutively. There are three arrays V, COL, and ROW. The ROW is sorted in increasing order, its size is M, and ROW[i] is an index in V and COL describing where row-i starts (i.e., if row i exists). We have that  $M_{i,*}$  is stored in V[ROW[i]:ROW[i+1]] and the column are at COL[ROW[i]:ROW[i+1]] and sorted increasingly. The CSR takes  $2 \times nnz + M$  space and a row vector of the matrix can be found in O(1).

The computation as  $y_i = \sum_i M_{i,j} * x_j$  is a sequence of dot products and the CSR representation is a natural:

$$Index = ROW[i] : ROW[i+1]$$
 
$$y_i = \sum_{i \in Index} V[i] * x_{COL[i]}$$

The matrix row is contiguous (in memory) and contiguous rows are contiguous. The access of the (dense) vector  $\mathbf{x}$  could have no pattern. The COO format could use a little preparation: For example, we can sort the array by row and add row information to achieve the same properties of CSR; however transposing a COO matrix is just a swap of the array ROW and COL. Think about matrix multiply. As today, each dot product achieves peak performance if the reads of the vector  $\mathbf{x}$  are streamlined as much as possible and so the reads of the vector V. If we have multiple cores, each could compute a sub set of the  $y_i$  and a clean data load balancing can go a long way. If we have a few functional units, we would like to have a constant stream of independent \* and \* operations but with data already in registers: that is, data pre-fetch will go a long way especially for  $\mathbf{x}_{COL[i]}$ , which may have an irregular pattern.

### 3 RANDOMIZATION

We refer to *Randomization* as row or column permutations of the matrix  $\mathbb{M}$  (thus a permutation of y and x) and we choose these by a pseudo-random process. Why we want to introduce uncertainty? The sparsity of our matrix  $\mathbb{M}$  has a pattern representing the nature of the original problem; such a pattern may exploit the wrong computation for an architecture; we could break such a pattern so that the only property left is a uniform distribution (of some sort). We must avoid the worst case and we would opt for an average case instead and we could do this to a class of  $\mathbb{M}$ . This is the gist.

If we know the matrix  $\mathbb{M}$  and we know the architecture, preconditioning must be a better solution. Well, it is. If we run experiments long enough, we choose the best permutations for the architecture, permute  $\mathbb{M}$ , and go on testing the next. On one end, preconditioning exerts a full understanding of both the matrix (the problem) and how the final solution will be computed (architecture). This is the culminating point of knowing and we must strive to it. On the other end, the simplicity of a random permutation requires no information about the matrix, the vector, and the architecture. Such a simplicity can be exploited directly in HW. We are after an understanding when randomization is just enough: we want to let the hardware do its best with the least effort, or at least with the appearance to be effortless. Also we shall show there are different flavors of random.

Interestingly, this work stems from a sincere surprise about randomization efficacy and its application on custom SpMV. Here, we want to study this problem systematically so that to help future hardware designs. Intuitively, if we can achieve a uniform distribution of the rows of matrix  $\mathbb{M}$  we can have provable expectation of its load balancing across multiple cores. If we have a uniform distribution of accesses on  $\mathbf{x}$  we could exploit column load balancing and exploit better sorting algorithms: in practice the reading of  $\mathbf{x}_{COL[i]}$  can be reduces to a sorting and we know that  $\mathbf{x}_{LOL[i]}$  manuscript submitted to ACM

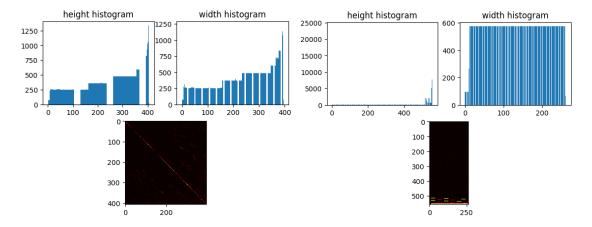

Fig. 1. Left: OPF 3754. Right: LP OSA 07. These are histograms where we represent normalized buckets and counts

different sparsity may require different algorithms. This is a lot to unpack but this translates as better performance of the sequential algorithm without changing the algorithm.

We will show that (different) randomness affects architectures and algorithms differently making it a suitable optimization especially when the application and hardware are at odds. We want to show that there is a randomness hierarchy that we can distinguish as global and local; there are simple-to-find cases where the sparsity breaks randomness and the matrix has to be split into components. We want to show that this study uses common tool, open software tools and sometimes naive experiments; however, we can infer properties applicable to proprietary and custom solutions.

## 4 ENTROPY

Patterns in sparse matrices are often visually pleasing, see Figure 1 where we present the height histogram, the width histograms and a two-dimensional histogram as heat map. We will let someone else using AI picture classification. Intuitively, we would like to express a measure of uniform distribution and here we apply the basics: *Entropy*. Given an histogram  $i \in [0, M-1]$   $h_i \in \mathbb{N}$ , we define  $S = \sum_{i=0}^{M-1} h_i$  and thus we have a probability distribution function  $p_i = \frac{h_i}{S}$ . The *information* of bin i is defined as  $I(i) = -\log_2 p_i$ . If we say that the stochastic variable X has PDF  $p_i$  than the entropy of X is defined as.

$$H(x) = -\sum_{i=0}^{M-1} p_i \log_2 p_i = \sum_{i=0}^{M-1} p_i I(i) = E[I_x]$$
 (1)

The maximum entropy is when  $\forall i, p_i = p = \frac{1}{M}$ ; that is, we are observing a uniform distributed event. There is no conceptual difference when the PDF represents a two dimensional distribution. Thus our randomization should aim at higher entropy numbers.

The entropy for matrix LP OSA 07 is 8.41 and for OPF 3754 is 8.39. A single number is satisfying because concise.

# 5 UNIFORM DISTRIBUTION

We know that we should **not** compare the entropy numbers of two matrices because entropy does not use any information about the order of the buckets only their probabilities. By construction, the matrices are quite different in Manuscript submitted to ACM

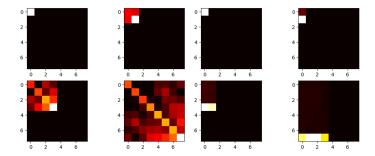

Fig. 2. Hierarchical 2D entropy for OPF 3754 (left) and LP OSA 07 (right).

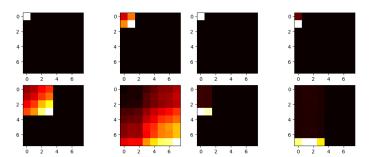

Fig. 3. Hierarchical 2D entropy after row and column random permutation for OPF 3754 (left) and LP OSA 07 (right).

sparsity and in shapes, however their entropy numbers are very close. To appreciate their difference, we should compare their distributions by Jensen-Shannon measure (which is a symmetric measure, please do not use Kullback-Leibler KL divergence). Or we could use a representation of a hierarchical 2d-entropy, see Figure 2, where the entropy is split into 2x2, 4x4 and 8x8 (or fewer if the distribution is not square). We have a hierarchical entropy heat maps.

We can see a more granular entropy summarizes better the nature of the matrix. In this work, the entropy vector is used mostly for visualization purpose more than for comparison purpose. Of course, we can appreciate how the matrix LP OSA 07 has a few very heavy rows and they are clustered. This matrix will help us showing how randomization need some tips. Now we apply row and column random permutation once by row and one by column: Figure 3: OPF has now entropy 11.27 and LP 9.26. The numerical difference is significant. The good news is that for entropy, being an expectation, we can use simple techniques like bootstrap to show that the difference is significant or we have shown that Jensen-Shannon can be used and a significance level is available. What we like to see is the hierarchical entropy heat map is becoming *more* uniform for at least one of the matrix.

In practice, permutations need some help especially for relatively large matrices. As you can see, the permutation affects locally the matrix. Of course, it depends on the implementation of the random permutation (we use numpy for this) but it is reasonable a slightly modified version of the original is still a random selection but unfortunately they seem more likely than they should. We need to compensate or help the randomization so that this current implementation does not get too lazy.

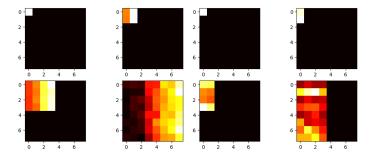

Fig. 4. Hierarchical 2D entropy after height gradient based shuffle and row random permutation for OPF 3754 (left) and LP OSA 07 (right).

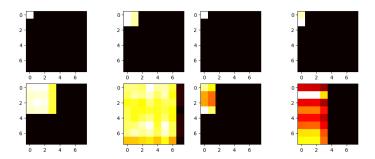

Fig. 5. Hierarchical 2D entropy after height and width gradient shuffle and row and column random permutation for OPF 3754 (left) and LP OSA 07 (right).

If we are able to identify the row and column that divide high and low density, we could use them as pivot for a shuffle like in a quick-sort algorithm. We could apply a sorting algorithm but its complexity will the same of SpMV. We use a gradients operations to choose the element with maximum steepness, Figure 4 and 6

LP achieves entropy 8.67 and 9.58 and OPF achieves 10.47 and 11.40.

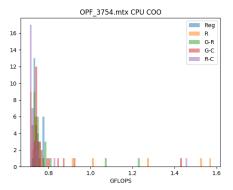

If the goal is to achieve a uniform matrix sparsity, it seems that we have the basic tools to compute and to measure such a sparsity. We admit that we do not try to find the best permutation. But our real goal is to create a work bench where randomization can be tested on different architectures and different algorithms. A randomization with a measurable uniform distribution is preferable than just random.

# **6 MEASURING THE RANDOMIZATION EFFECTS**

Whether or not this applied to the reader, when we have timed execution of algorithms we came to expect variation. The introduction of randomization may hide behind the ever present random behavior, after all these are algorithms on *small* inputs and small error can be comparable to the overall execution time. Here, we must address this concern even before describing the experiments.

First, every algorithm is run between 1000 and 5000 times. The time of each experiments is in the seconds, providing a granularity we are confident that error in measuring time (per se) is under control. Thus, for each experiment we provide an average execution time: we measure the time and we divide by the number of trials. Cold starts, the first

Manuscript submitted to ACM

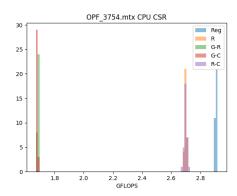

Fig. 6. CPU COO (left) and CPU CSR (left) for OPF 3754

iteration, are still accounted. To make the measure portable across platform we present GFLOPS, that is, Giga  $(10^{12})$  floating operations per second: 2 \* nnz divided by the average time in seconds.

Then we repeat the same experiment 32 times. Permutations in *numpy* Python uses a seed that is time sensitive: thus every experiment is independent from the previous. The number 32 is an old statistic trick and it is a minimum number of independent trials to approximate a normal distribution. In practice, they are not but the number is sufficient for most of the cases and it is an excellent starting point.

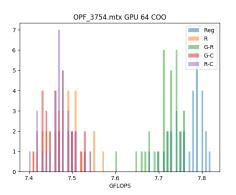

A short hand legend: **Reg** is the matrix without any permutation and thus is the regular; **R** stands for random Row permutation; **G-R** stands for gradient-based row shuffle and random row permutation; **G-C** stands for gradient-based column shuffle and random column permutation; **R-C** stands for random row and column permutation. This legend is used in the pictures to be concise, in the tables in the following sections, we use a verbose description. We shall clarify the gradient based approach in the experimental results section 9. Intuitively, we help the random permutation by a quick targeting of high and low volume of the histogram (and thus the matrix).

In Figure 6, We show CPU performance using COO and CSR SpMV algorithms for the matrix OPF 3754. We can see that the CSR algorithms are consistent and the Regular (i.e., the original) has always the best performance. For the COO, permutations introduce a long tails. In Figure 7, Randomization is harmful to the GPU implementation. If the load balance is fixed (i.e., by dividing the matrix by row and in equal row), randomization is beneficial.

For matrix LP OSA 07, randomization helps clearly only for CPU CSR as we show in Figure 11

An example, the matrix MULT DCOP 01, is where randomization is useful for the CPU, GPU, and the parallel version Figure 15, 16, and 19 and the gains can be up to 10-15%. Consider, we can achieve these improvements without any insights to the architecture, the alfgorithms and their relationships.

What does it mean when randomization does not work? The matrices we use in this work are not chosen randomly (pun not intended), they are the matrices that are difficult to handle in our custom SpMV engines using a combination of sorting networks and systolic arrays. If randomization does not work in our simplified work bench, will not work in our specialized architecture because the reorganization of the matrix or the input and output vector does not have the necessary parallelism, data locality, and data streaming. We need to do something else. In this case disrupting the memory pattern is not sufficient. Thus, if we cannot beat the pattern, we must exploit it, well not in this work.

### 7 WORKLOADS

In the previous sections, we defined what we mean for randomization and we present our tools of tricks for the measure of the effects of randomization. Here we describe the work loads, the applications, we use to test the effects of the randomization.

# 7.1 Python COO and CSR algorithms

The simplicity to compute the SpMV by the code z = A \* b in Python is very rewarding. By change of the matrix storage format, AC = A.tocsr(); z = AC \* b, we have a different algorithm. The performance exploitation is moved to the lower level. The CSR implementation is often two times faster but there are edge cases where the COO and COO with randomization can go beyond and be surprisingly better: MUL DCOP 03 is an example where COO can do well.

Intuitively, Randomization can affect the performance because the basic implementation is a sorting algorithm and it is a fixed algorithm. There are many sorting algorithms and each can be optimal for a different initial distribution. If we knew what is the sorting algorithm we could tailor the input distribution. Here we just play with it.

# 7.2 Parallel CSR using up to 16 cores

Python provides the concept of Pool to exploit a naive parallel computation. We notice that work given to a Pool are split accordingly to the number of elements to separate HW cores. We also noticed that the work load can move from a core to another, thus may not be ideal. Also we notice that Pool introduce a noticeable overhead: a Pool of 1, never achieves the performance of the single thread z = AC \* b. Using Pool allows us to investigate how a naive row partitioning without counting can scale up with number of cores. Randomization goal is to distribute the work uniformly: a balanced work distribution avoid the unfortunate case where a single core does all the work.

# 7.3 GPU COO and CSR algorithms

In this work, we use AMD GPUs and *rocSPARSE* is their current software. The software has a few glitches but overall can be used for different generation of AMD GPUs. We use the COO and CSR algorithms and when possible or useful we provide performance measure for single and double precision (mostly double precision). The ideas of using different Manuscript submitted to ACM

GPUs is important to verify that the randomization can be applied independently of the HW. We are not here to compare performance with other GPUs or even between CPUs and GPUs.

The performance of the CSR algorithm is about two time faster than the COO. Most of the algorithms use the CSR format to count the number of sparse elements in a row and thus they can decide the work load partition accordingly. Counting give you an edge but without changing the order of the computation there could be cases where the work load is not balanced and a little randomization could help and it helps.

#### 7.4 Randomization sometimes works

For the majority of the cases we investigated and reported in the following sections, Randomization does not work and it affects the performance negatively. However, there are cases where randomization does work and does work for different algorithms and architectures. If you are in the business of preconditioning, permutations are pretty cheap. Of course, permutation changes the computation order and this may affect precision: for low precision matrices such as half floating point (fp16) or smaller we may re-evaluate. For the semiring (min,+) and for integer arithmetic the computation order does not matter.

### 8 CALL FOR A DIFFERENT STRATEGY

We want to find out randomization techniques that are suitable for custom hardware but also what are the most common and simple heuristics that can justified for any hardware.

## 9 EXPERIMENTAL RESULTS

The main hardware setup is a AMD Threadripper with 16 cores and Radeon GPUs Vega 20, 2xFiji, and 2xEllesmere. Vega is designed so that 64bit precision is not neglected and has 1TB/s HBM memory, Fiji has 512GB/s HBM and more 32bit precision oriented, and the Ellesmere uses DDR.

There are 4 basic randomization formats:

- Random Row Permutation, we take the original matrix and permute the rows.
- Random Row and Column Permutation, we take the original matrix and permute the row and the column.
- Gradient based row permutation, we compute the row histogram and we compute the gradient:  $h_{i+1} h_i$ . We find a single point where the gradient is maximum, this is the pivot for a shuffle like a magician would shuffle a deck of cards. Then the two parts are permuted.
- Gradient based row and column permutation, As above but also for the columns.

For large matrices (large number of columns and rows) a permutation tends to be a close version to the original. It is still considered a random permutation. The gradient allows us to at least quickly describe two area of the original matrix where there is a clear and de-marked density variation, for example to uniform distributed sub matrices but one denser than the other. A shuffle redistribute every other sample/card to different parts and these can be permuted locally.

We report in the following the performance results, we introduce a \* following the best performance.
